GAS NOISE SOURCE, NEON, PULSE

DESCRIPTION

This tube is designed for use as a noise source in microwave measurements. It is constructed for use with the RG-50/U waveguide to provide noise in the 5.85-8.20 kMc waveband. When used in a 10° or 15° E-plane mount assembly, it functions as an untuned termination over the entire recommended transmission bandwidth of the guide. It is a cold cathode type noise source designed primarily for pulse operation but may be used for continuous service with somewhat reduced life.

OPERATING CHARACTERISTICS

The use of pure inert gas eliminates the dependence of noise output on the operating temperature. The noise source is available for measurement instantaneously with little change due to ambient temperature variations. The performance of the tube is non-critical with respect to variations in the discharge current over a wide range.

The average voltage standing wave ratio (VSWR) over the recommended transmission bandwidths of the guides is a maximum of 1.15. The excess noise ratio, 10 log \( \frac{V_{off}}{V_{on}} \), is 17.98 ± .3db.

The circuit of Figure 1 is a basic starting and operating circuit. The pentode or beam tube acts as a switch interrupting the current flow in \( L_1 \) when the cut-off bias switch is closed. The resultant voltage spike developed is impressed across the noise tube. The current is limited by \( R_3 \) to rated value. Capacitor \( C_1 \) flattens the pulse peak and assists in initiating the noise tube discharge. \( C_1 \) must not be large enough to lower the voltage spike below the firing voltage of the noise tube and must be of high voltage rating. Current through the beam tube is adjusted by \( R_1 \) to provide rated choke current. If the application requires only intermittent starting, the hard tube may be replaced by a mercury switch.

For most normal pulse applications, this basic circuit can be modified to drive the grid of the switch tube with pulses, thus pulsing the noise output. For high repetition rates or for control of pulse shape, a circuit, similar to that shown in Figure 2, which insures extinguishing of the noise tube current, is necessary.

Note: If the anode current during the "on time" of a square pulse (of greater than 100 microsec duration) is nominally the same as the rated D.C. anode current, the tube drop during this period will be approximately the same as the rated D.C. tube drop.
