Standard Telephones and Cables Limited
FOOTSCRAY, KENT, ENGLAND

INTRODUCTION: The Brimar 6BA6 is an indirectly-heated variable-mu RF pentode. The heater is intended for operation in parallel with other valves in AC operated equipment. The valve is designed for use as an RF or IF amplifier; suitable shielding and short leads provide a good performance in high frequency circuits. This report contains characteristics of the valve and details of its performance.

DESCRIPTION: The valve consists of a miniature variable-mu RF pentode having a mutual conductance of the order of 4 mA/V and is mounted in a standard T5$\frac{1}{2}$ bulb and fitted with a B7G standard base.

CHARACTERISTICS:
- Indirectly-heated oxide-coated cathode.
- Heater Voltage: 6.3 volts
- Heater Current: 0.3 amperes
- Max. DC Heater-Cathode Potential: 250 volts

DIMENSIONS:
- Max. Overall Length: 2-1/8 ins.
- Max. Seated Height (excluding tip): 1-19/32 ins.

BASE:
- Type B7G

BASE CONNECTIONS:
- Pin 1 Control Grid
- Pin 2 Suppressor and Internal Shield
- Pin 3 Heater
- Pin 4 Heater
- Pin 5 Anode
- Pin 6 Screen
- Pin 7 Cathode

MAXIMUM RATINGS:
- Max. Anode Voltage: 300 volts
- Max. Screen Voltage: 125 volts
- Max. Screen Supply Voltage: 300 volts
- Max. Anode Dissipation: 3.0 watts
- Max. Screen Dissipation: 0.6 watts

CAPACITIES (approx.):
- Measured with no external shield.
  - Pentode Connected:
    - Input: 5.5 pF
    - Output: 5.0 pF
    - Grid-Anode: 0.0035 pF max.
  - Grounded Grid Operation:
    - Anode-Cathode: 0.01 pF
    - Input: 6.0 pF
    - Output: 5.6 pF
**CHARACTERISTIC CURVES:** Attached to this report are curves showing:

a. Anode current \((I_a)\) plotted against control grid voltage for various screen voltages (Curve No. 309·28).

b. Mutual conductance \((g_m)\) and anode impedance \((r_a)\) against control grid voltage for fixed and sliding screen voltage operation (Curve No. 309·29).

c. Anode current plotted against anode voltage for a screen voltage of 125 volts (Curve No. 309·30) and for a screen voltage of 100 volts (Curve No. 309·31).

**TYPICAL OPERATING CONDITIONS**

**Class A Amplifier** (suppressor connected to cathode):

**Operation as an RF or IF Amplifier:** The valve is intended primarily for service in the above application. It is recommended that cathode bias always be used rather than fixed bias and that normally the suppressor grid and the internal shield be connected to the cathode at the socket. The valve should be so mounted that the grid and anode leads to the remainder of the circuit run in opposite directions to each other and are as short as is practicable in order to ensure high gain with stability. The decoupling components should also be chosen and located with care for similar reasons.

When used in VHF receivers the valve may be employed with normal pentode connections or as a grounded grid amplifier at frequencies of the order of 100 Mc/s. It is also very efficient as an IF amplifier using intermediate frequencies around 10 Mc/s. When so employed a stage gain of 44 times can be expected with a total bandwidth of 200 Kc/s for 3 db down with IF coils of Q 70 and tuning capacity 50 pF.
For those applications where very high frequencies are employed and changes in input capacity and input impedance are undesirable, it is advisable that grid bias be applied to the control grid and suppressor grid simultaneously, the control grid being biased to a value of approximately 2.5% of that applied to the suppressor grid.

Curves are attached to this report showing input capacity and input impedance plotted against control grid voltage for the sliding screen conditions at 50 Mc/s (Curve No. 309:35), and similarly but for auto bias (Curve No. 309:36). Curves Nos. 309:37 and 309:38 are similar to the above but taken at a frequency of 90 Mc/s.

**Operation as a Resistance-Capacity Coupled Amplifier:** Although the valve has a variable-mu control grid characteristic it may still be used for small inputs as an RC coupled amplifier; curves are attached to this report covering this application. Curve No. 309:32 is plotted with an anode load resistor of 100,000 ohms and shows the relationship between anode current, screen current and control grid voltage for various screen voltages. Curves Nos. 309:33 and 309:34 are similar to the above but plotted for anode load resistors of 220,000 and 470,000 ohms respectively. The method of using these curves to design an RC coupled amplifier is described below.

If, for example, it is desired to use the valve at a supply voltage of 250 volts with an anode load resistor of 220,000 ohms and a succeeding valve grid leak of 470,000 ohms, then an examination of Curve No. 309:33 shows that grid current \( I_{g1} \) commences at about \(-0.7\) volts, hence a grid bias should be chosen such that the signal never swamps the grid to a value of much less than \(-1\) volt. If a value of \(-1.5\) volts is taken then fairly straight portions of the \( I_s/V_a \) curves are available for \( V_{g2} \) 30 volts. Taking the operating point as \( V_{g2} \) 30 volts and \( V_{g1} \) \(-1.5\) volts, the plate current will be 0.81 mA and the screen current \( I_{g2} \) 0.28 mA, hence the cathode resistor will be:

\[
\frac{1.5 \times 1000}{0.81 + 0.28}
\]

or 1380 ohms;

In practice 1500 ohms would be used. The screen dropping resistor would be:

\[
\frac{250 - 30}{0.28} \times 1000, \text{ or } 785,000 \text{ ohms.}
\]

Again the nearest preferred value would be 680,000 ohms. If the grid has a peak AF input of \( \pm 0.5 \) volts as a maximum, the anode current will vary from 0.60 mA at a grid voltage of \(-2.0\) volts to 1.07 mA at \(-1\) volt, hence a change of 0.47 mA in 220,000 is 104 volts peak-peak. This is an output of 52 volts peak and a voltage gain of 104.

As allowance must be made for the succeeding valve grid leak the above values will be reduced by a factor of:

\[
\frac{470,000}{470,000 + 220,000}
\]

or 0.68,

hence the actual operating gain will be 70 and the output voltage 50 volts peak for an input of 0.7 volts peak. An estimate of the distortion can be obtained by calculating in a similar manner the voltage gain for the positive swing (\(-1.5\) to \(-1.0\) volts) and the negative swing (\(-1.5\) to \(-2.0\) volts) separately, the resultant figures indicating the amount by which one peak is amplified more than the other.
